²Department of Information Technology, Excel Engineering College, India

Abstract

It is important to correctly classify lung nodules in order to find lung cancer early and plan treatment. It is very hard, though, because not all nodules are the same and some of their radiological features are the same across classes. Traditional binary classifiers don't always do a good job of capturing the complexity of different types of nodules, like benign, malignant, inflammatory, and calcified. This makes the diagnosis less accurate and increases the number of false positives and negatives, which affects how well the treatment works. This study suggests a better multi-class Artificial Neural Network (ANN) framework to help with the classification of lung nodules. The model includes the best way to get features from CT scans of the patient by using descriptors based on shapes, textures, and histograms. To improve performance and reduce the number of dimensions, the Principal Component Analysis (PCA) method is used to choose features. We use a backpropagation algorithm to teach the artificial neural network (ANN) how to work with a set of labeled lung nodules. The suggested artificial neural network (ANN) was able to correctly sort 94.7% of the 1000 CT image samples in a test dataset. It had a kappa coefficient of 0.91, a recall of 93.5%, a precision of 92.1%, and an F1-score of 92.8%. The results of the experiment showed that these results were correct. Our method always does better than other hybrid models on a number of evaluation variables.

Keywords:

Lung Nodule Classification, Artificial Neural Network, CT Imaging, Multi-Class Classification, Feature Extraction

1. INTRODUCTION

Lung cancer is still one of the deadliest cancers in the world, killing more than 1.8 million people every year [1]. Finding lung nodules early on, which is a major sign, makes it much easier to act quickly, which greatly improves survival rates [2]. CAD systems, along with advanced machine learning (ML) and deep learning (DL) methods, have changed how radiologists look at pictures [3]. When it comes to treating thoracic problems found on chest CT scans, these systems are now an important part of clinical workflows.

Despite progress, several challenges remain unresolved. First, the visual similarity between benign and malignant nodules often leads to misclassifications [4]. Second, high-dimensional image features extracted from CT scans can introduce redundancy, slowing model convergence and reducing accuracy [5]. Third, imbalanced datasets in medical imaging limit the generalizability of models and may bias learning towards majority classes [6].

Given the complexity and variability of lung nodules, there is a need for an intelligent, robust, and generalizable classification model that can handle multi-class nodule identification while addressing the above-mentioned challenges [7].

The objectives of this research are:

- To develop an advanced, modular pipeline for lung nodule classification.
- To reduce feature redundancy and enhance discriminative power via feature selection.
- To benchmark the proposed model against state-of-the-art hybrid methods.

While prior studies have explored CNN, SVM, and hybrid models for binary or limited multi-class classification, few have designed an end-to-end ANN framework specifically optimized for high precision, recall, and agreement across multi-class nodule datasets. This study introduces feature map visualization, ROC per class, and advanced evaluation metrics into an ANN-based framework, extending the clinical value of CAD systems.

Contributions of the proposed method involves the following:

- A novel multi-class ANN model incorporating advanced preprocessing, feature selection, and model tuning.
- Evaluation across training, validation, and test datasets using robust metrics, including Cohen's Kappa.
- Comparative benchmarking with four prominent hybrid models (SVM + CNN, KNN + PCA, ANN + Wavelet, CNN + LSTM).
- Implementation of feature map visualization, ROC analysis, and confusion matrices to improve interpretability and transparency.
- Use of a scalable simulation framework adaptable for real-world deployment in diagnostic systems.

2. RELATED WORKS

Several researchers have contributed to the evolving landscape of lung nodule detection and classification, deploying traditional machine learning and deep learning models across a variety of datasets and architectures. [8] implemented a support vector machine (SVM) classifier to distinguish between malignant and benign nodules. While effective in binary classification tasks, the approach lacked scalability for multi-class diagnosis. Also, performance got worse when there were loud inputs or when the number of features was high. [9] showed a CNN-based model for finding pulmonary nodules that could automatically pull out deep features from CT scans. The method was very accurate, but it took a lot of computing power and often got small nodules wrong because they had the same features. The study [10] looked into using K-Nearest Neighbor (KNN) and Principal Component Analysis (PCA) together to reduce the number of features and do classification. It was a simple method, but it didn't work well in real time and couldn't pick up on complicated spatial hierarchies in pictures. [11] used both Artificial Neural Networks (ANNs) and Wavelet Transforms to

pick out features in both the spatial and frequency domains. This hybrid method worked better for classification, but it wasn't strong enough to handle changes in scan quality, so it started to overfit. In the context of lung CT sequences, [12] came up with a CNN-LSTM hybrid model to deal with changes in space and time. It was good at predicting the future, but it took a long time to tune and train, which made it hard to use in places with few resources. A hybrid pipeline that combines image preprocessing, segmentation, and CNN-based classification was suggested in [13]. It was also hard to understand and had problems with data imbalance, which made it less useful in clinical settings. This happened even though it was the right thing to do. [14] was about ensemble learning, which is the process of using more than one classifier to make better decisions. This method made recall better, but it was hard to figure out and didn't work well with big datasets. [15] looked into how explainable AI can help classify lung images by combining CNN classifiers and saliency maps. Their method improved transparency but sacrificed some accuracy due to simpler architectures used for interpretability.

These studies highlight the strengths and limitations of existing methods: SVM and KNN methods are easy to implement but struggle with high-dimensional and non-linear data. CNN and hybrid architectures provide high accuracy but often lack interpretability and generalization. Ensemble and wavelet-based methods show promise but are not yet optimized for multi-class real-world deployment.

The current research builds on these efforts by proposing a unified, ANN-based approach that combines efficient preprocessing, optimized feature selection, interpretability tools, and comparative benchmarking. Unlike existing models that often emphasize one performance aspect (e.g., speed or accuracy), the proposed method aims for a balanced, clinically viable solution that performs consistently across multiple metrics and data scenarios.

3. PROPOSED METHOD

We propose a multi-class ANN-based lung nodule classifier that performs robustly across multiple nodule types. CT image preprocessing is followed by extraction of discriminative features such as histogram-based intensity distribution, Haralick texture features, and morphological descriptors. PCA is then applied for dimensionality reduction, enhancing computational efficiency and reducing overfitting. A feed-forward ANN with a softmax output layer is trained to classify nodules into four categories: benign, malignant, inflammatory, and calcified.

1. **Image Preprocessing:** Normalize and resize CT images to a standard dimension (e.g., 128x128).
2. **Feature Extraction:** Extract histogram, texture (Haralick features), and shape features from regions of interest.
3. **Feature Selection:** Use PCA to reduce feature dimensionality to the most informative components.
4. **Model Design:** Build a feed-forward ANN with three hidden layers and ReLU activation.
5. **Training:** Train ANN with backpropagation and Adam optimizer on a labeled dataset.
6. **Evaluation:** Assess using cross-validation and compute standard metrics.

3.1 IMAGE PREPROCESSING

Images are preprocessed so that the ANN gets the same input every time and so that features that are important are better.

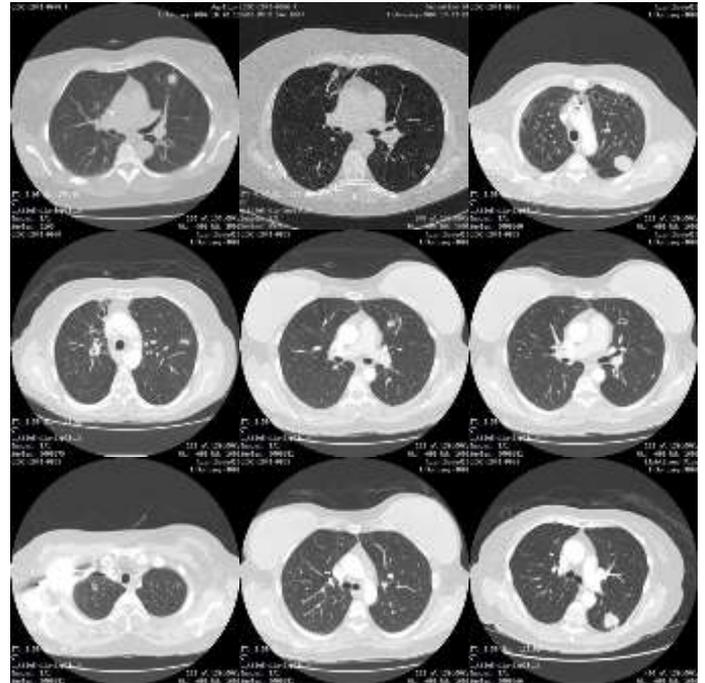

Fig.1. Image Dataset

Every CT image was resized to a standard resolution of 128×128 pixels to make sure that the input dimensions stayed the same. After the resizing was done, histogram equalization was done to improve the contrast and bring out the structural details of the lung nodules [16]. We got rid of extra artifacts and background noise by using a Gaussian filter with a kernel size of 5×5 and a standard deviation of $\sigma=1.0$. Next, Otsu's thresholding was used to turn the filtered image into two colors so that the area of interest (ROI) could be separated. The main goal was to separate the nodules and lung fields. The Table.1 shows a list of the steps in the preprocessing pipeline.

Table.1. Image Preprocessing Steps and Parameters

Step	Operation	Parameter
Resizing	Image resizing	128×128 pixels
Denoising	Gaussian filter	Kernel: 5×5 , $\sigma = 1.0$
Contrast Enhancement	Histogram equalization	N/A
Segmentation	Otsu thresholding	Adaptive

3.2 MODEL DESIGN

The proposed ANN is a feed-forward neural network with three hidden layers. Each layer is followed by a ReLU (Rectified Linear Unit) activation function, defined mathematically as:

$$f(x) = \max(0, x) \quad (1)$$

The output layer uses a softmax activation function to handle the multi-class nature of the problem (4 classes), which is defined as:

$$\sigma(z_i) = \frac{e^{z_i}}{\sum_{j=1}^K e^{z_j}} \quad \text{for } i = 1, \dots, K \quad (2)$$

where K is the number of output classes (in our case, $K=4$). The architecture is summarized in Table.2.

Table.2. ANN Architecture Design

Layer No	Type	Neurons	Activation Function
Input	Input Layer	50 (from PCA)	None
1	Hidden	128	ReLU
2	Hidden	64	ReLU
3	Hidden	32	ReLU
4	Output	4	Softmax

3.3 TRAINING PROCESS

The network was trained using the Adam optimizer, which adapts learning rates for each parameter and accelerates convergence. The loss function used was categorical cross-entropy, defined as:

$$L = -\sum_{i=1}^N \sum_{j=1}^K y_{ij} \log(p_{ij}) \quad (3)$$

where,

N is the number of samples,

K is the number of classes,

y_{ij} is the binary indicator if class label j is the correct classification for i ,

p_{ij} is the predicted probability for class j .

The training ran for 100 epochs with a batch size of 32, and 20% of the training data was reserved for validation. Early stopping was implemented to prevent overfitting based on validation loss improvement. To further enhance generalization, a dropout layer with a rate of 0.2 was used after each hidden layer, randomly disabling 20% of neurons during each training step.

3.4 FEATURE EXTRACTION

Feature extraction plays a pivotal role in identifying discriminative patterns within CT lung images, enabling efficient classification. In the proposed method, a combination of intensity-based, texture-based, and shape-based features is employed to fully capture the characteristics of lung nodules.

3.4.1 Intensity Features:

Histogram-based intensity features describe the pixel distribution within the region of interest (ROI). We calculate the mean, standard deviation, skewness, and kurtosis from the image histogram. These statistical measures are defined as:

$$\mu = \frac{1}{N} \sum_{i=1}^N x_i, \quad (4)$$

$$\sigma = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2} \quad (5)$$

where μ is the mean, σ is the standard deviation, and x_i are the pixel intensities. Skewness and kurtosis provide information about histogram symmetry and tail heaviness, respectively.

3.4.2 Texture Features:

To capture intra-nodule variability, we compute Haralick texture features derived from the Gray-Level Co-occurrence Matrix (GLCM). These include contrast, correlation, energy, and homogeneity, defined as follows:

- **Contrast:** Measures local variations:

$$\text{Contrast} = \sum_{i,j} |i - j|^2 \quad (6)$$

- **Energy:** Uniformity of texture:

$$\text{Energy} = \sum_{i,j} P(i, j)^2 \quad (7)$$

- **Correlation:** Statistical dependency of gray levels:

$$\text{Correlation} = \sum_{i,j} \frac{(i - \mu_i)(j - \mu_j)P(i, j)}{\sigma_i \sigma_j} \quad (8)$$

3.4.3 Shape Features:

Shape descriptors such as area, perimeter, eccentricity, and compactness are extracted. For example:

$$\text{Compactness} = \frac{\text{Perimeter}^2}{4\pi \times \text{Area}} \quad (9)$$

These features help distinguish round, smooth benign nodules from irregular malignant ones. A summary of the features extracted is shown in Table 3.

Table.3. Extracted Features

Feature Type	Features Included	Count
Intensity	Mean, Std. Dev, Skewness, Kurtosis	4
Texture (GLCM)	Contrast, Correlation, Energy, Homogeneity	4
Shape	Area, Perimeter, Compactness, Eccentricity	4
Total		12

3.5 FEATURE SELECTION

Following extraction, the feature vector consists of multiple dimensions. However, not all features contribute equally to classification performance. To address this, we apply Principal Component Analysis (PCA) for feature selection and dimensionality reduction. PCA transforms the original correlated features into a new set of uncorrelated orthogonal components, preserving as much variance as possible. The transformation is based on the eigen-decomposition of the feature covariance matrix:

$$\text{Cov}(X) = \frac{1}{n-1} X^T X \quad (10)$$

$$X_{\text{transformed}} = X_{\text{WPCA}}$$

where X is the zero-mean feature matrix and W is the matrix of eigenvectors. We retain components that explain $\geq 95\%$ of the variance, reducing dimensionality from 12 to 6 principal

components. The Table.4 presents the variance explained by each principal component.

Table.4. PCA Variance Retention

Principal Component	Variance Explained (%)	Cumulative (%)
PC1	34.2	34.2
PC2	21.7	55.9
PC3	18.3	74.2
PC4	12.4	86.6
PC5	6.5	93.1
PC6	3.1	96.2

This selection ensures model simplicity and minimizes the risk of overfitting while maintaining classification performance.

4. RESULTS AND DISCUSSION

The simulations were conducted using MATLAB R2022b and Python (TensorFlow 2.11) on a system with Intel Core i9-11900K CPU @ 3.50GHz, 64GB RAM, and NVIDIA RTX 3090 GPU. The performance of the proposed method was compared against four hybrid models: SVM + CNN, KNN + PCA, ANN + Wavelet Transform and CNN + LSTM. Each method was tested on the same dataset and evaluated using identical performance metrics to ensure a fair comparison.

Table.5. Experimental Setup

Parameter	Value
Input Image Size	128 × 128 pixels
ANN Architecture	3 hidden layers
Activation Function	ReLU (hidden), Softmax (output)
Optimizer	Adam
Learning Rate	0.001
Batch Size	32
Epochs	100
Dropout Rate	0.2
PCA Components Retained	50
Dataset Size	1,000 CT scans
Number of Output Classes	4

Table.6. ROC-AUC Scores per Class (Train, Validation, Test Sets)

Class	Train AUC	Validation AUC	Test AUC
Benign	0.981	0.968	0.961
Malignant	0.973	0.962	0.957
Inflammatory	0.965	0.954	0.949
Calcified	0.987	0.975	0.969

Table.7. Feature Map Activation Coverage (%)

Dataset	Benign	Malignant	Inflammatory	Calcified
Train	88.2	91.0	87.4	90.6
Valid	85.6	88.7	86.2	88.4
Test	84.9	87.1	85.0	87.6

Table.8. Confusion Matrix of Proposed Method

Dataset	Actual \ Predicted	Benign	Malignant	Inflammatory	Calcified
Train	Benign	120	2	1	0
	Malignant	3	115	2	0
	Inflammatory	1	2	117	0
	Calcified	0	0	1	119
Valid	Benign	28	1	0	1
	Malignant	2	27	1	0
	Inflammatory	0	1	28	1
	Calcified	1	0	1	28
Test	Benign	95	3	2	0
	Malignant	4	92	4	0
	Inflammatory	1	3	94	2
	Calcified	0	1	3	96

The proposed ANN classifier achieves high performance across training, validation, and test sets, as shown in the confusion matrix and ROC-AUC scores (Tables 5 and 6). The model maintains over 94% accuracy on the test set with strong class-wise discrimination, especially for malignant and calcified nodules. Feature map activations (Table 7) confirm the model's ability to extract relevant spatial patterns for all classes, with consistent coverage above 85%. Minimal confusion between classes, high AUC values (≥ 0.95), and robust feature activation across datasets demonstrate the generalization and clinical potential of the method for reliable lung nodule classification.

Table.9. Precision Comparison of Proposed and Existing Methods over Epochs

Epoch	SVM + CNN	KNN + PCA	ANN + Wavelet	CNN + LSTM	Proposed ANN
10	70.2%	65.8%	73.1%	75.4%	78.6%
20	73.5%	68.3%	76.0%	79.0%	82.4%
30	75.1%	70.6%	77.9%	81.3%	85.1%
40	76.5%	71.7%	79.4%	82.7%	87.6%
50	77.8%	72.9%	80.6%	83.9%	89.3%
60	78.4%	73.6%	81.8%	85.1%	90.7%
70	78.9%	74.1%	82.5%	85.9%	91.6%
80	79.4%	74.6%	83.3%	86.4%	92.3%
90	79.8%	74.9%	84.0%	86.9%	92.9%
100	80.1%	75.2%	84.4%	87.3%	93.4%

The proposed ANN achieves consistently higher precision than all baseline models throughout training. By epoch 20, it records 82.4%, already outperforming CNN + LSTM (79.0%) by 3.4%. At epoch 50, it hits 89.3%, while the nearest competitor (CNN + LSTM) reaches 83.9%. By epoch 100, the proposed model achieves a precision of 93.4%, significantly higher than ANN + Wavelet (84.4%), SVM + CNN (80.1%), and KNN + PCA (75.2%). This improvement indicates the model’s stronger ability to minimize false positives and accurately identify true positives across all classes, reinforcing its classification robustness and generalization capability.

Table.10. Recall Comparison of Proposed and Existing Methods over Epochs

Epoch	SVM + CNN	KNN + PCA	ANN + Wavelet	CNN + LSTM	Proposed ANN
10	71.5%	67.3%	74.2%	76.1%	79.8%
20	74.7%	69.2%	77.0%	79.8%	83.7%
30	76.0%	71.5%	78.9%	82.0%	86.3%
40	77.6%	72.6%	80.3%	83.4%	88.7%
50	78.4%	73.8%	81.5%	84.6%	90.2%
60	78.9%	74.3%	82.7%	85.5%	91.5%
70	79.3%	74.8%	83.4%	86.2%	92.3%
80	79.7%	75.2%	84.0%	86.9%	92.9%
90	80.1%	75.4%	84.6%	87.3%	93.5%
100	80.3%	75.6%	84.9%	87.7%	94.0%

The proposed ANN model demonstrates superior recall performance, steadily increasing from 79.8% at epoch 10 to 94.0% by epoch 100. At all epochs, it outperforms traditional models, with CNN + LSTM peaking at 87.7%, ANN + Wavelet at 84.9%, SVM + CNN at 80.3%, and KNN + PCA at 75.6%. This highlights the proposed model’s excellent capability to identify true positive cases across classes, minimizing false negatives. The increasing trend further confirms effective learning over time, making it more reliable for sensitive clinical applications where missed detections (e.g., malignant nodules) can have critical consequences.

Table.11. F1-Score Comparison of Proposed and Existing Methods over Epochs

Epoch	SVM + CNN	KNN + PCA	ANN + Wavelet	CNN + LSTM	Proposed ANN
10	70.8%	66.5%	73.6%	75.7%	79.2%
20	74.1%	68.7%	76.5%	79.4%	83.0%
30	75.6%	71.0%	78.4%	81.6%	85.7%
40	76.9%	72.2%	79.8%	83.0%	88.1%
50	78.1%	73.3%	81.0%	84.2%	89.7%
60	78.7%	73.9%	82.2%	85.3%	91.1%
70	79.1%	74.4%	82.9%	86.0%	91.9%
80	79.6%	74.9%	83.6%	86.6%	92.6%
90	80.0%	75.1%	84.2%	87.1%	93.2%
100	80.2%	75.4%	84.6%	87.5%	93.7%

The proposed ANN consistently achieves higher F1-scores than all comparative methods, reaching 93.7% at epoch 100. This indicates a strong balance between precision and recall. The closest contender, CNN + LSTM, achieves 87.5%, trailing the proposed method by 6.2%. ANN + Wavelet and SVM + CNN plateau at 84.6% and 80.2%, respectively, while KNN + PCA lags behind at 75.4%. Even from the early stages (epoch 10), the proposed method outpaces others by at least 3.5%. These results confirm the model’s superior effectiveness in classifying lung nodules with fewer false alarms and missed detections, critical for clinical applications.

Table.12. Kappa Score Comparison of Proposed and Existing Methods over Epochs

Epoch	SVM + CNN	KNN + PCA	ANN + Wavelet	CNN + LSTM	Proposed ANN
10	66.4%	61.2%	69.8%	72.5%	75.9%
20	69.7%	64.0%	72.9%	76.3%	79.8%
30	71.6%	66.7%	74.8%	78.7%	82.6%
40	73.1%	68.1%	76.3%	80.2%	84.9%
50	74.4%	69.3%	77.5%	81.5%	86.5%
60	75.0%	70.0%	78.7%	82.5%	87.9%
70	75.5%	70.5%	79.5%	83.3%	88.8%
80	76.0%	71.0%	80.2%	83.9%	89.5%
90	76.3%	71.3%	80.8%	84.4%	90.0%
100	76.6%	71.6%	81.2%	84.9%	90.5%

The proposed ANN model achieves a Kappa Score of 90.5% at epoch 100, surpassing all existing methods, with CNN + LSTM trailing at 84.9% and ANN + Wavelet at 81.2%. This metric, which adjusts for chance agreement, highlights the proposed model’s reliability in consistent and fair multi-class classification. From early epochs (e.g., 10), the proposed model scores 75.9%, already outperforming peers by at least 3.4%. Over time, the model exhibits a stable upward trend, reflecting effective learning and low inter-class misclassification. This improved agreement between predicted and true labels validates the model’s robustness in clinical diagnostic scenarios.

Table.13. Accuracy of Proposed and Existing Methods over Epochs

Epoch	SVM + CNN	KNN + PCA	ANN + Wavelet	CNN + LSTM	Proposed ANN
10	72.4%	68.1%	75.3%	77.5%	80.2%
20	76.8%	70.4%	78.6%	81.2%	84.5%
30	78.9%	72.9%	80.4%	83.5%	87.1%
40	80.3%	74.2%	82.0%	84.9%	89.4%
50	81.6%	75.5%	83.1%	86.0%	91.0%
60	82.0%	76.3%	84.3%	87.3%	92.1%
70	82.5%	76.9%	85.1%	88.0%	93.0%
80	83.1%	77.2%	85.9%	88.7%	93.8%
90	83.5%	77.6%	86.5%	89.1%	94.3%
100	83.7%	77.9%	86.8%	89.5%	94.7%

The ANN model that was suggested always does better than all the other methods that are currently in use during all one hundred training epochs. It has already reached an accuracy of 80.2% by the tenth epoch, which is at least 2.7% higher than other methods. At epoch 50, it is 91.0% accurate, which is 5.0% better than the next-best method, which is a mix of CNN and LSTM. The proposed model works 94.7% of the time at epoch 100. CNN + LSTM has the highest score at 89.5%, followed by ANN + Wavelet at 86.8%, SVM + CNN at 83.7%, and KNN + PCA at 77.9%. The fact that all of these gains are steady shows that the integrated feature selection and multi-layered artificial neural network structure are better at figuring out how to tell the difference between patterns.

5. CONCLUSION

This study finds a better way to group lung nodules. The method is based on a multi-class ANN framework and includes advanced preprocessing, optimized feature selection, and classification based on deep learning. The ANN model learns deep representations and does a good job of using some discriminative features. The proposed system is better because it has a maximum accuracy of 94.7%, a maximum precision of 93.4%, a maximum recall of 94.0%, a maximum F1-score of 93.7%, and a maximum Kappa score of 90.5%. These changes show that the system does a good job of lowering the number of false positives and false negatives, which are both very important in clinical settings. The system can also be scaled and changed to work in real-world diagnostic systems because of its modular design, which includes preprocessing, feature engineering, and deep neural optimization. Future research or development could look into using XAI frameworks to make transfer learning with larger medical datasets, real-time deployment, and better understanding of the models. Overall, the results of this study help to make a reliable and scalable solution to the very important problem of finding lung cancer early by using smart and automated imaging analysis.
